Baseline 54 +12

OVERALL

61

Baseline 69 -8

Based on repeat AI readings of this week's photos, changes smaller than ± 5.3 points are within normal measurement variation, not confirmed change.

MEASUREMENT QUALITY

Confidence **88%** (High)

Photo quality **84**

Visible scalp **27%**

BASELINE

LATEST

Visual change map

Baseline vs. latest photo per region, pixel-aligned and compared. Warmer colors show where the image visibly changed — this maps visible change, not hair count or density.

Scalp visibility map

Color analysis of your crown photo, not a clinical assessment — areas that look scalp-colored rather than hair-colored are marked red. It can also catch skin or background that isn't scalp, and struggles with light or gray hair, so treat this as a rough visual aid.

Hair Density Estimate (hairs/cm²)

Not a clinical measurement. This is the AI's own rough visual guess at hair density from your photo — not a computed measurement — so treat it as a talking point, not a number to track precisely week to week.

From the crown photo.

80 hairs/cm²

AI's own confidence: 70%.

"The image clearly shows a significant area of visible scalp with sparse hair coverage on the top of the head, indicating thinning."

Trend over time

 No confirmed trend yet

"Overall (smoothed)" averages each point with the one before it, so a single noisy reading doesn't look like a real swing. The badge above fits a line across every scan and only calls it a real trend once it clears normal measurement noise -- not just whether the last two points moved.

Photo timeline

Best photo per captured region for each scan (up to 6), alongside that scan's measurements.

Latest insight

Your current photo shows a noticeable reduction in overall hair volume and density on top of your head, particularly visible around the temples, compared to your baseline. This aligns well with your reported density drop of -15 and coverage drop of -25 against baseline. The change map clearly highlights significant pixel changes (warm yellow/red) concentrated at the crown and temples, confirming these are the primary areas where less hair volume is now visible. While your frontal hairline score is stable (+0), the recession at the temples is more apparent. Focus on gently handling your hair, especially around the temples and top, to minimize any further physical stress on these areas.

Front: The front region shows good density and coverage at 82, with a slight decrease from the previous scan, yet the photo looks robust.

Left: The left side shows moderate density and coverage at 62, a significant drop from the previous scan, consistent with visible thinning in the photo.

Right: The right region has high density and coverage at 84-85, with a minor decrease from the last scan, and the photo shows dense hair.

Crown: The crown metrics are very low at 28, indicating significantly reduced density and coverage, which is clearly visible in the photo.

Hairline: The hairline region shows moderate density and coverage at 52, with a substantial drop from the previous scan, which is consistent with the visible recession.

This report presents objective photographic measurements only. It does not diagnose hair loss or provide medical advice. Based on 10 scan(s); latest averaged across all sharp frames captured (very blurry frames excluded).
